??

stringstream vs. string

stringstream vs. string

When should I use a stringstream?

1. Processing strings
   - Simplify “/./a/b/..” to “/a”
2. Formatting input/output
   - uppercase, hex, and other stream manipulators
3. Parsing different types
   - stringToInteger() from previous lectures

stringstream vs. string

When should I use a stringstream?

1. Processing strings
   - Simplify “/./a/b/..” to “/a”
2. Formatting input/output
   - uppercase, hex, and other stream manipulators
3. Parsing different types
   - stringToInteger() from previous lectures

If you’re just concatenating strings, str.append() is faster than using a stringstream!

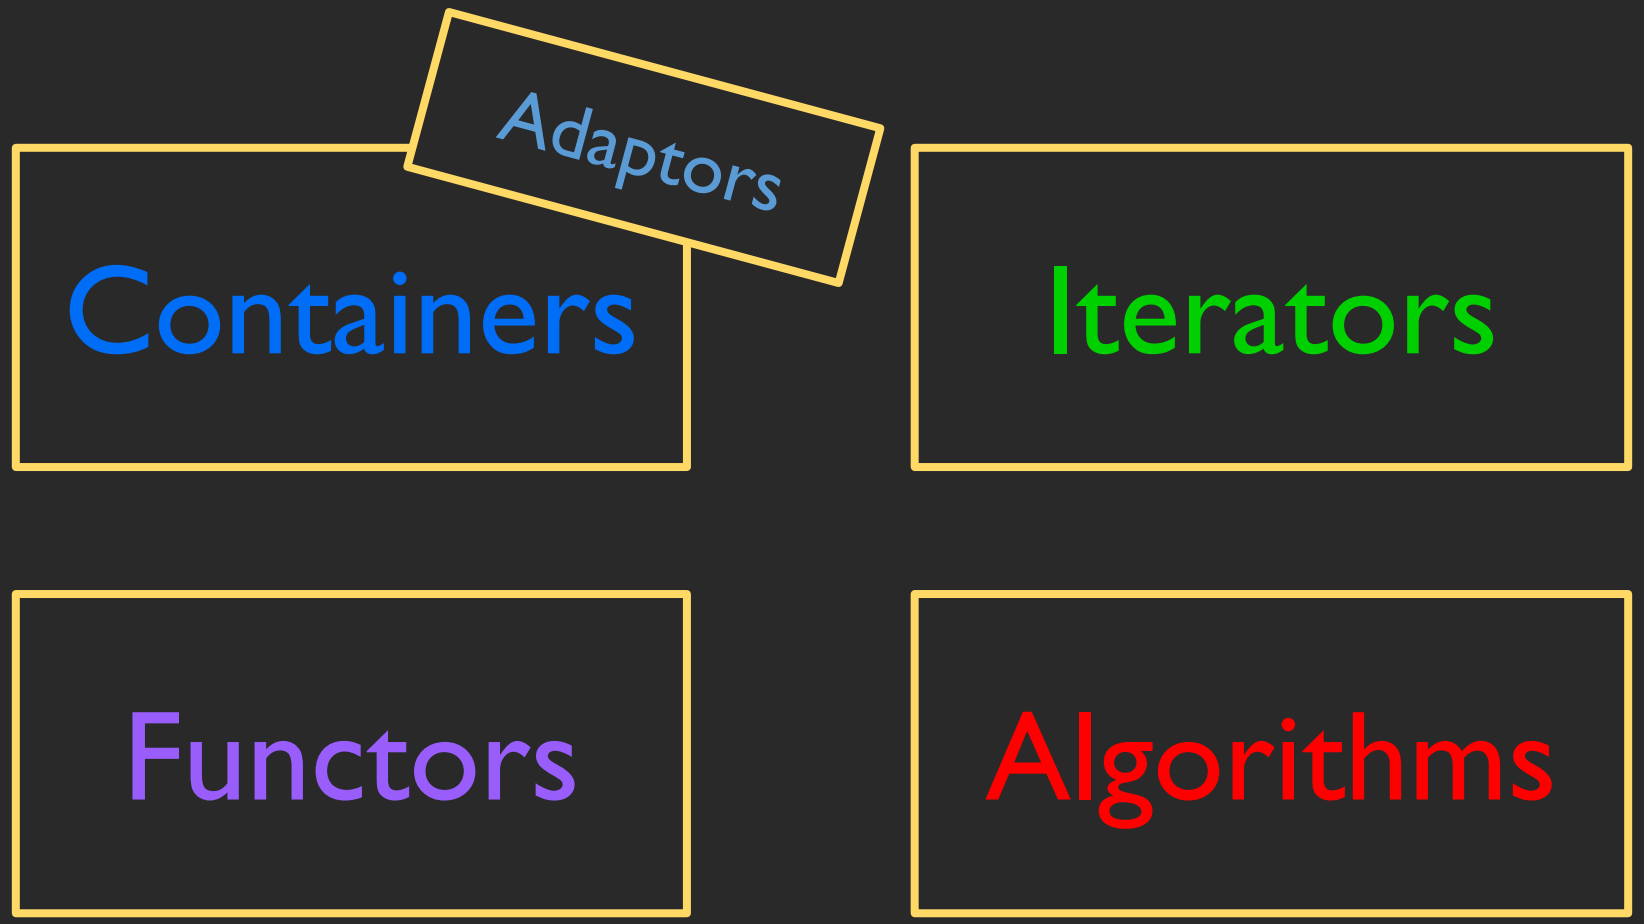
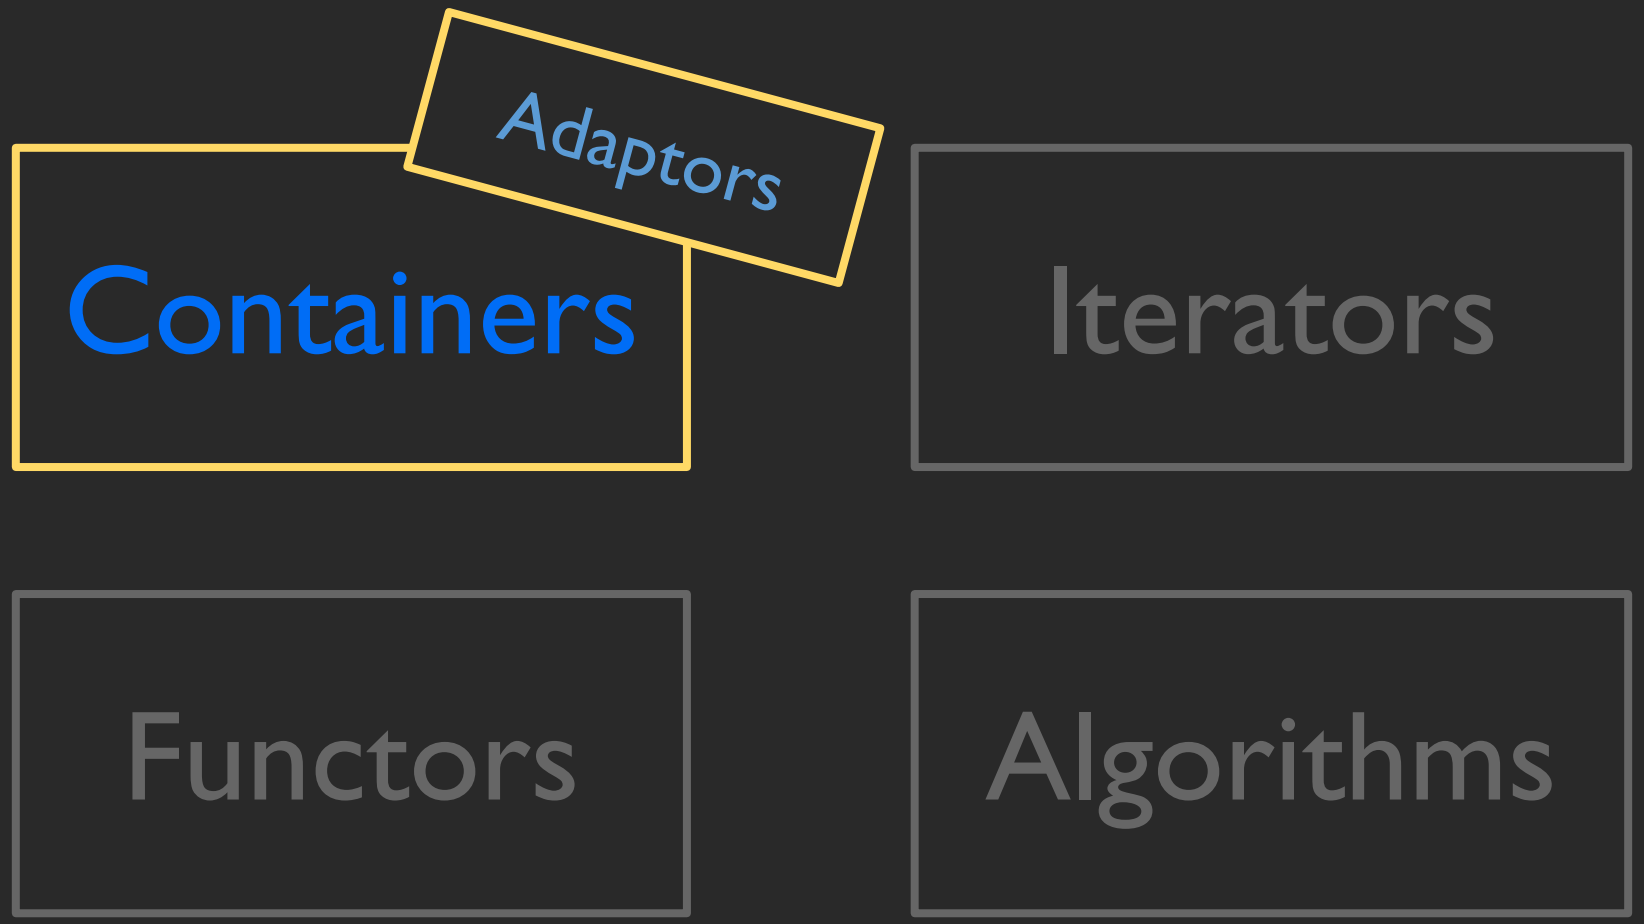
Functors

Algorithms

Overview of STL



Overview of STL



Sequence Containers

Sequence Containers

Provides access to sequences of elements.

Includes:

- `std::vector<T>`
- `std::deque<T>`
- `std::list<T>`
- `std::array<T>`
- `std::forward_list<T>`

```
std::vector<T>
```

std::vector<T>

A vector represents a sequence of elements of any type.

You specify the type when using the vector:

```
std::vector<int> vecInt;            // vector of ints
std::vector<string> vecStr;         // vector of string
std::vector<myStruct> vecStruct; // vector of myStructs
std::vector<std::vector<string>> vecOfVec; // vector of
                                           vector<string>
```

Stanford vs. STL: Part 1

Stanford vs. STL: Part 1

```
/*      Stanford C++ Version      */
Vector<int> v = { 1, 3, 7 };

v += 271;

cout << v[0] << endl;
cout << v[v.size() - 1] << endl;

Vector<int> first = v.subList(0, 2);
Vector<int> last  = v.subList(2);

v.remove(0);
```

Stanford vs. STL: Part 1

```
/*      Stanford C++ Version      */
Vector<int> v = { 1, 3, 7 };

v += 271;

cout << v[0] << endl;
cout << v[v.size() - 1] << endl;

Vector<int> first = v.subList(0, 2);
Vector<int> last  = v.subList(2);

v.remove(0);
```

```
/* Standard C++ Version */
std::vector<int> v = { 1, 3, 7 };
```

Stanford vs. STL: Part 1

```
/*      Stanford C++ Version      */
Vector<int> v = { 1, 3, 7 };

v += 271;

v.push_back(271);

cout << v.front() << endl;
cout << v.back() << endl;

// no such thing as a sublist

v.erase(v.begin());   // or v.pop_back()
```

Stanford vs. STL: Part 2

Stanford vs. STL: Part 2

```
/*      Stanford C++ Version          */
Vector<string> v = { "A", "B", "C" };

/* Counting for loop. */
for (int i = 0; i < v.size(); i++) {
    cout << v[i] << endl;
}

/* Range-based for loop. */
for (string elem: v) {
    cout << elem << endl;
}
```

Stanford vs. STL: Part 2

```
/*      Stanford C++ Version          */
Vector<string> v = { "A", "B", "C" };

/* Counting for loop. */
for (int i = 0; i < v.size(); i++) {
    cout << v[i] << endl;
}

/* Range-based for loop. */
for (string elem: v) {
    cout << elem << endl;
}
```

/* Standard C++ Version */

```
std::vector<string> v = { "A", "B", "C" };
```

Stanford vs. STL: Part 2

```
/*      Stanford C++ Version          */
Vector<string> v = { "A", "B", "C" };

/* Counting for loop. */
for (int i = 0; i < v.size(); i++) {
    cout << v[i] << endl;
}

/* Range-based for loop. */
for (string elem: v) {
    cout << elem << endl;
}
```

/* Standard C++ Version */

```
std::vector<string> v = { "A", "B", "C" };

// Basically the same
for (size_t i = 0; i < v.size(); ++i) {
    cout << v[i] << endl;
}
```

Stanford vs. STL: Part 2

```
/*      Stanford C++ Version          */
Vector<string> v = { "A", "B", "C" };

/* Counting for loop. */
for (int i = 0; i < v.size(); i++) {
    cout << v[i] << endl;
}

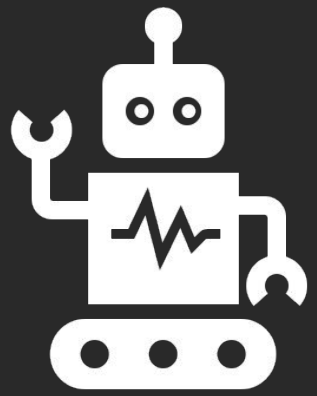
/* Range-based for loop. */
for (string elem: v) {
    cout << elem << endl;
}
```

/* Standard C++ Version */

```
std::vector<string> v = { "A", "B", "C" };

// Basically the same
for (size_t i = 0; i < v.size(); ++i) {
    cout << v[i] << endl;
}

// The same
for (string elem: v) {
    cout << elem << endl;
}
```



Example

Standard C++ Vector in (Basic) Action

Why the Difference?

Why doesn't `std::vector` bounds check by default?

Hint: Remember our discussion of the philosophy of C++

Why the Difference?

Why doesn't `std::vector` bounds check by default?

Hint: Remember our discussion of the philosophy of C++

If you write your program correctly, bounds checking will just slow your code down.

Play around with the `std::vector`!

http://www.cplusplus.com/reference/vector/vector/

Summary of Stanford `Vector<T>` vs `std::vector<T>`

What you want to do	Stanford Vector<int>	std::vector<int>
Create an empty vector	`Vector<int> v;`	`vector<int> v;`
Create a vector with n copies of zero	`Vector<int> v(n);`	`vector<int> v(n);`
Create a vector with n copies of a value k	`Vector<int> v(n, k);`	`vector<int> v(n, k);`
Add k to the end of the vector	`v.add(k);`	`v.push_back(k);`
Clear vector	`v.clear();`	`v.clear();`
Get the element at index i (* Verify that i is in bounds!)	`int k = v.get(i);` `int k = v[i];`	`int k = v.at(i);` `int k = v[i];` (*)
Check if the vector is empty	`if (v.isEmpty()) ...`	`if (v.empty()) ...`
Replace the element at index i (* Verify that i is in bounds!)	`v.get(i) = k;` `v[i] = k;`	`v.at(i) = k;` `v[i] = k;` (*)

STL特殊之处：用.at()越界会报警；用[]越界不会报警

One Important Similarity

What you want to do	Stanford Vector<int>	std::vector<int>

vec.push_front(7);
```

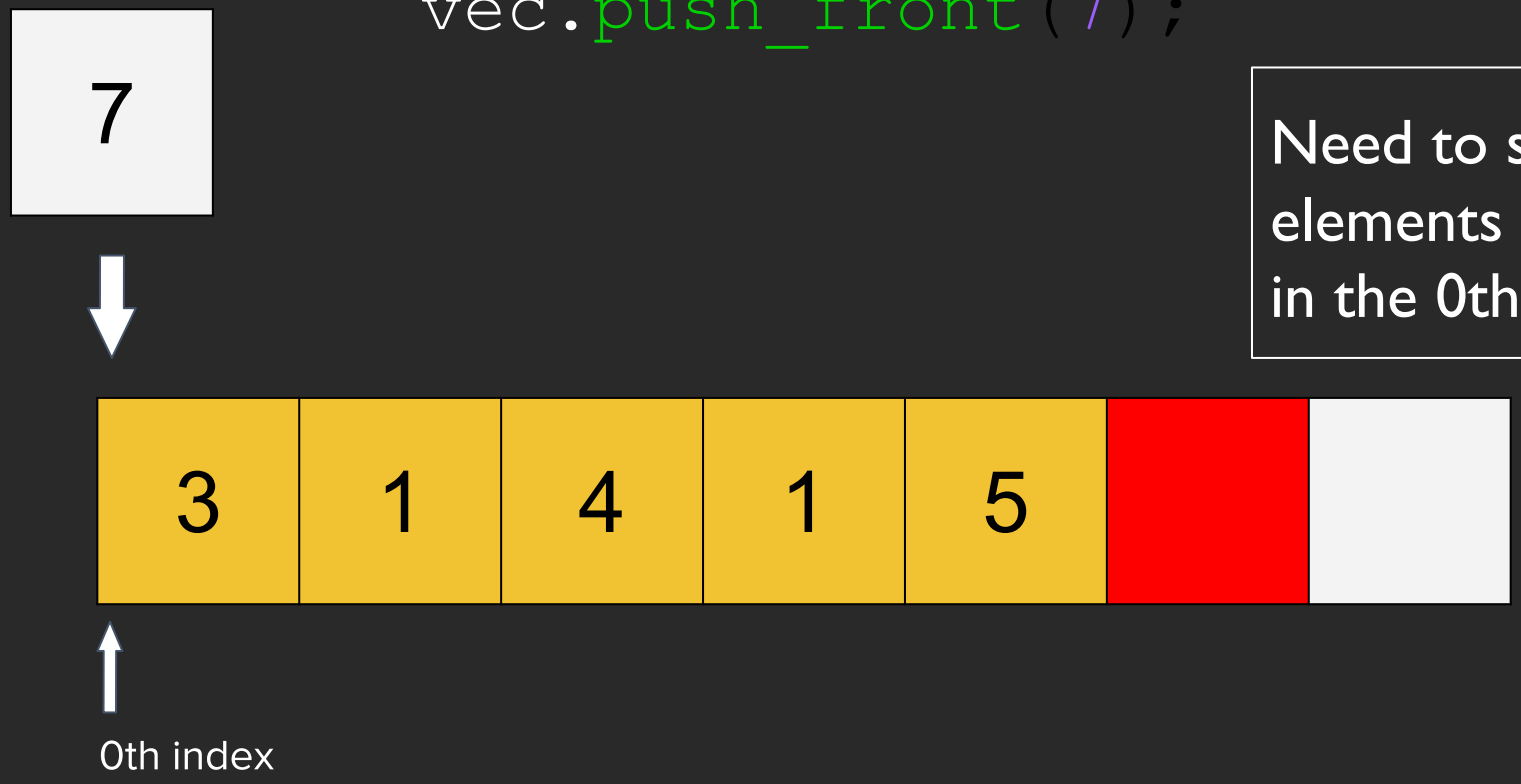
Need to shift these elements up to make space in the 0th position.

What if we had a `push_front()`?

Suppose `push_front` existed and we used it.

Let's look at a small vector:

```
vec.push_front(7);
```



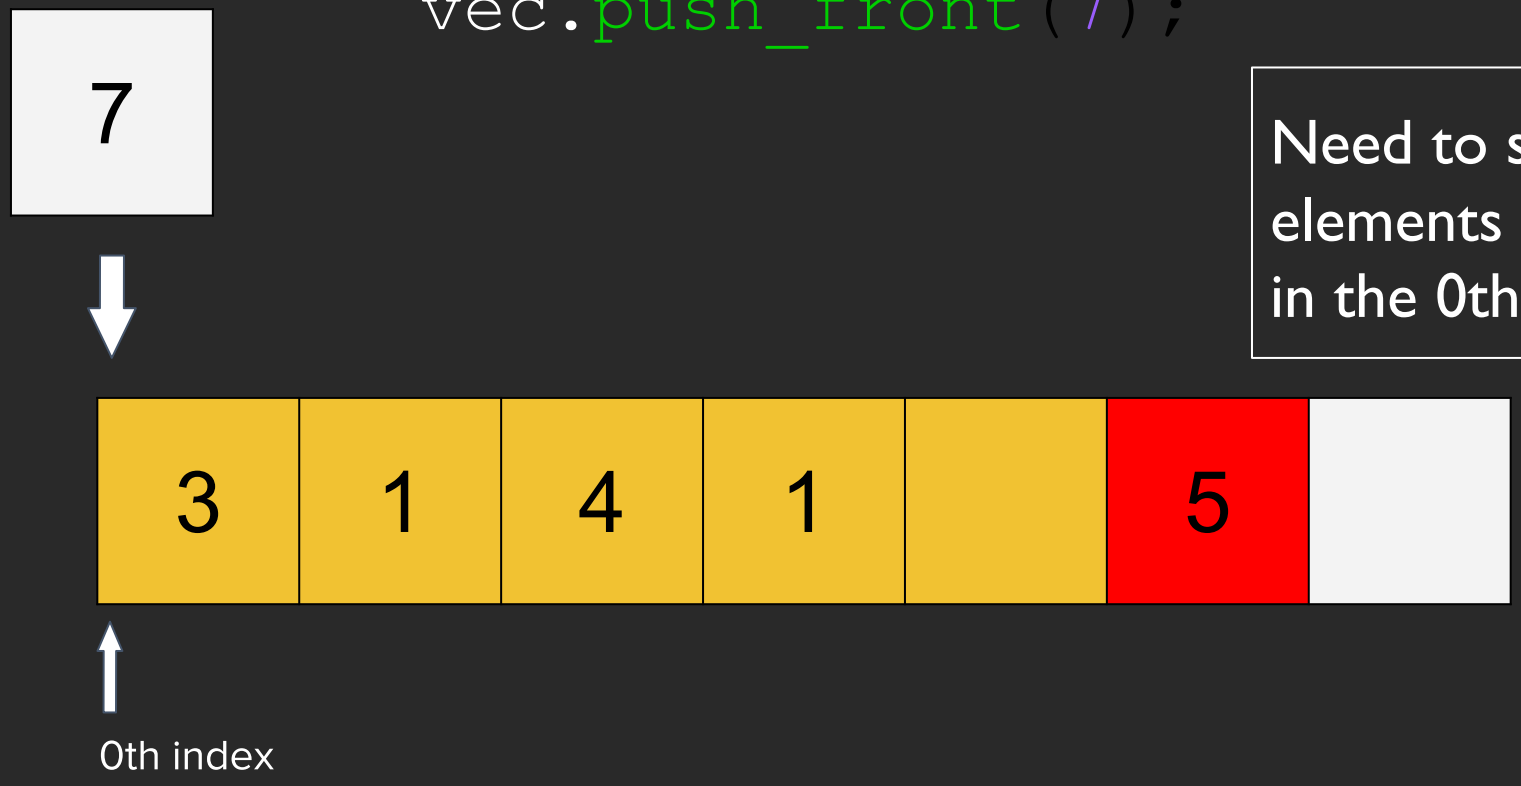
Need to shift these elements up to make space in the 0th position.

What if we had a `push_front()`?

Suppose `push_front` existed and we used it.

Let's look at a small vector:

```
vec.push_front(7);
```



Need to shift these elements up to make space in the 0th position.

What if we had a `push_front()`?

Suppose `push_front` existed and we used it.

Let's look at a small vector:

```
vec.push_front(7);
```

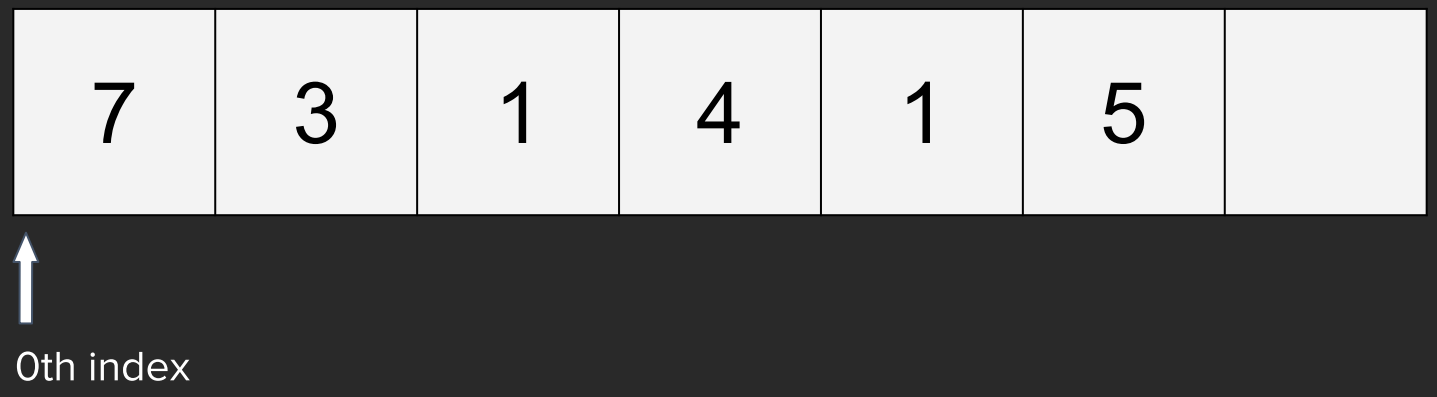
Now we can insert the new element.

What if we had a `push_front()`?

Suppose `push_front` existed and we used it.

Let's look at a small vector:

```
vec.push_front(7);
```



What if we had a `push_front()`?

7	3	1	4	1	5	

0th index

Conclusion: `push_front()` is slow!

A vector is the prime tool of choice in most applications!

- Fast
- Lightweight
- Intuitive

However, we just saw vectors grow efficiently in only one direction.

Sometimes it is useful to be able to `push_front` quickly!

C++ has a solution!

```
std::deque<T>
```

`std::deque<T>`

Pronounced “deck”.

Stands for a double ended queue.

Does everything a vector can do

AND

Unlike a vector, it is possible (and *fast*) to `push_front` and `pop_front`!

Syntax of `std::deque<T>`

/* Standard C++ Version */

```
std::deque<int> d = { 1, 3, 7 };

d.push_back(271);
d.push_front(-1);

cout << d.front() << endl;
cout << d.back() << endl;

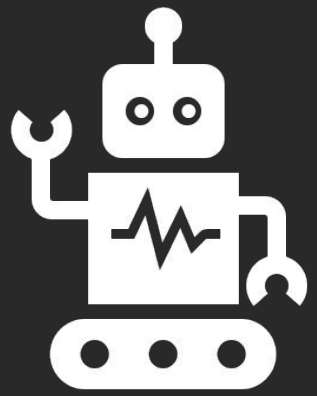
d.pop_back();
d.pop_front();
```

```
// d = {1, 3, 7}

// d = {1, 3, 7, 271}
// d = {-1, 1, 3, 7, 271}

// prints -1
// prints 271

// d = {-1, 1, 3, 7}
// d = {1, 3, 7}
```

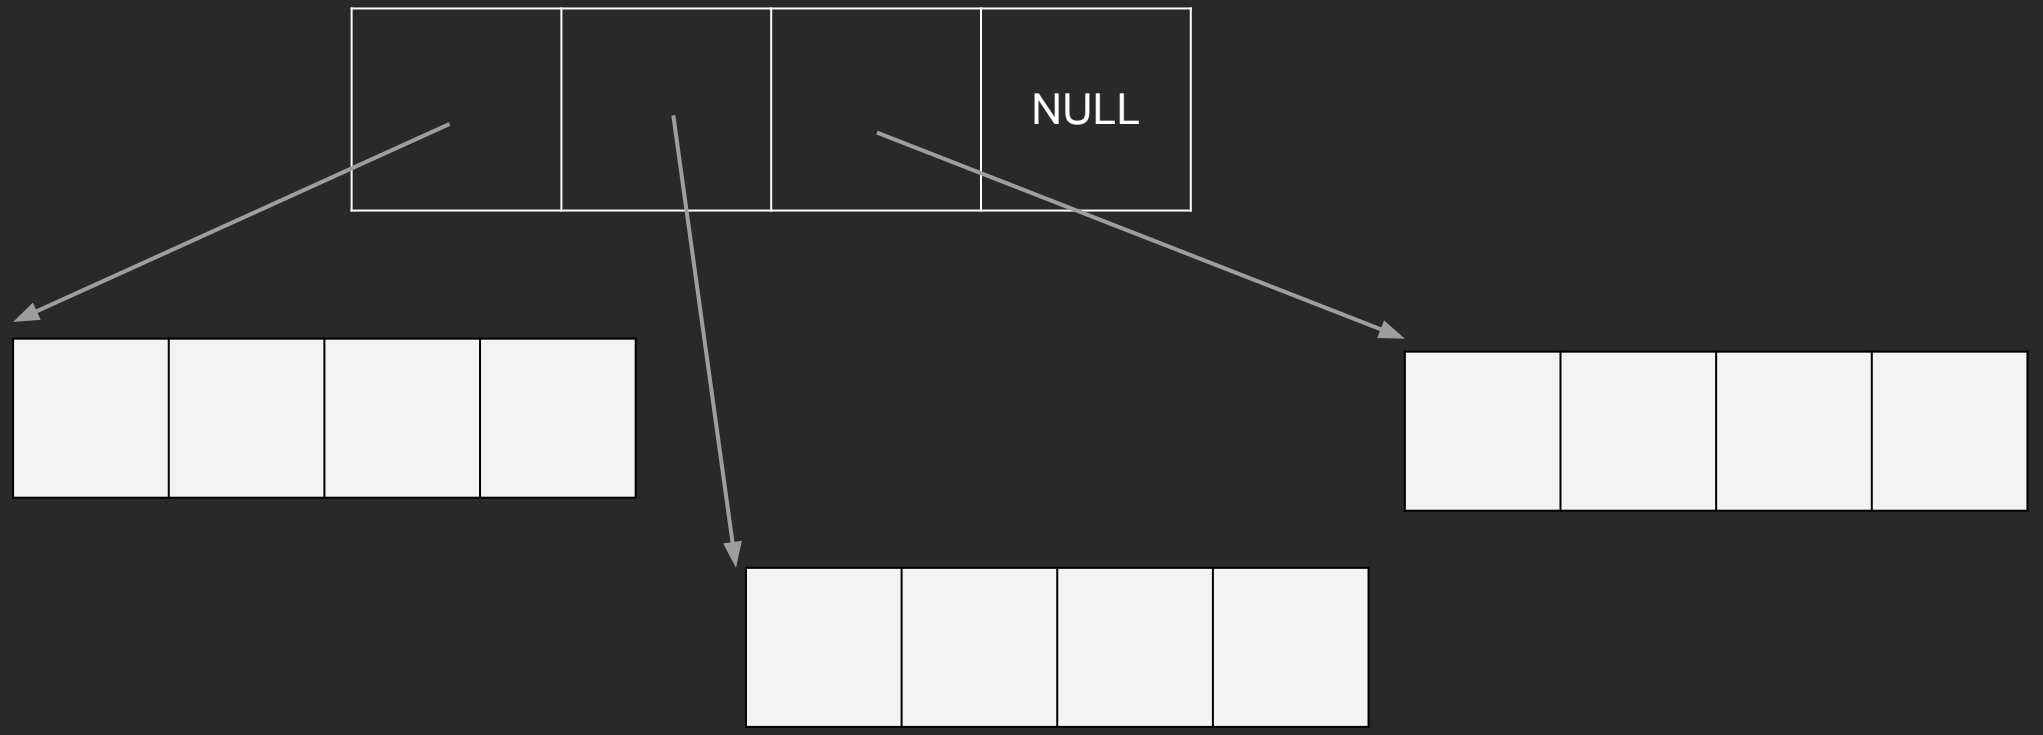


Example

Vector vs. Deque: `push_front`

How does `std::deque<T>` work?

There is no single specific implementation of a deque, but one common one might look like this:



How does `std::deque<T>` work?

How does `std::deque<T>` work?

There is no single specific implementation of a deque, but one common one might look like this:

Wait a minute...

Question

If deque can do everything a vector can do and also has a fast `push_front`...

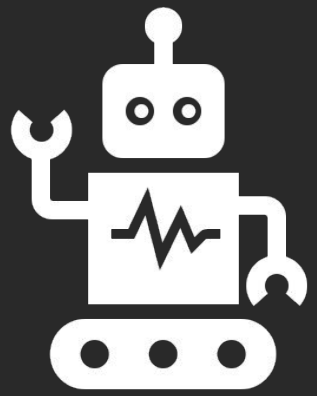
Why use a vector at all?

Downsides of `std::deque<T>`

Deques support fast `push_front` operations.

However, for other common operations like element access, vector will always outperform a deque.

Let’s see this in action!



Example

Vector vs. Deque: Element Access

Which to Use?

“vector is the type of sequence that should be used by default... deque is the data structure of choice when most insertions and deletions take place at the beginning or at the end of the sequence.”

Container Adaptors

How can we implement stack and queue using the containers we have?

Container Adaptors

How can we implement stack and queue using the containers we have?

Stack:

Just limit the functionality of a vector/deque to only allow `push_back` and `pop_back`.

Queue:

Just limit the functionality of a deque to only allow `push_back` and `pop_front`.

Plus only allow access to top element

Container Adaptors

For this reason, stacks and queues are known as container adaptors.

std::stack

Defined in header <stack>

```
template<
    class T,
    class Container = std::deque<T>
> class stack;
```

The `std::stack` class is a container adapter that gives the programmer the functionality of a stack - specifically, a FILO (first-in, last-out) data structure.

The class template acts as a wrapper to the underlying container - only a specific set of functions is provided. The stack pushes and pops the element from the back of the underlying container, known as the top of the stack.

Template parameters

T - The type of the stored elements. The behavior is undefined if T is not the same type as `Container::value_type`. (since C++17)

Container - The type of the underlying container to use to store the elements. The container must satisfy the requirements of `SequenceContainer`. Additionally, it must provide the following functions with the usual semantics:

- `back()`
- `push_back()`
- `pop_back()`

The standard containers `std::vector`, `std::deque` and `std::list` satisfy these requirements.

std::queue

Defined in header <queue>

```
template<
    class T,
    class Container = std::deque<T>
> class queue;
```

The `std::queue` class is a container adapter that gives the programmer the functionality of a queue - specifically, a FIFO (first-in, first-out) data structure.

The class template acts as a wrapper to the underlying container - only a specific set of functions is provided. The queue pushes the elements on the back of the underlying container and pops them from the front.

Template parameters

T - The type of the stored elements. The behavior is undefined if T is not the same type as `Container::value_type`. (since C++17)

Container - The type of the underlying container to use to store the elements. The container must satisfy the requirements of `SequenceContainer`. Additionally, it must provide the following functions with the usual semantics:

- `back()`
- `front()`
- `push_back()`
- `pop_front()`

The standard containers `std::deque` and `std::list` satisfy these requirements.

Example

The Power of the C++ STL

Where we are going...

Here is a program that generates a vector with random entries, sorts it, and prints it, all in one go!

```
const int kNumInts = 200;
std::vector<int> vec(kNumInts);
std::generate(vec.begin(), vec.end(), rand);
std::sort(vec.begin(), vec.end());
std::copy(vec.begin(), vec.end(),
          std::ostream_iterator<int>(cout, "\n"));
```
